## **Application run states**

# Application lifecycle

```
$ python gasset.py parameters.csv simAsset.m
```

```
[...]
```

Application objects can be in one of several states.

NEW	19/19	(100.0%)
RUNNING	0/19	(0.0%)
STOPPED	0/19	(0.0%)
SUBMITTED	0/19	(0.0%)
TERMINATED	0/19	(0.0%)
TERMINATING	0/19	(0.0%)
UNKNOWN	0/19	(0.0%)
total	19/19	(100.0%)

(A session-based script prints a table of all managed applications and their states.)

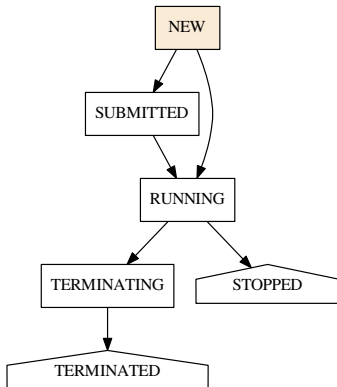

```
>>> print (app.execution.state)
' TERMINATED '
```

The current state is stored in the `.execution.state` instance attribute.

## Reference:

<http://gc3pie.readthedocs.io/en/master/programmers/api/gc3libs.html#gc3libs.Run.state>

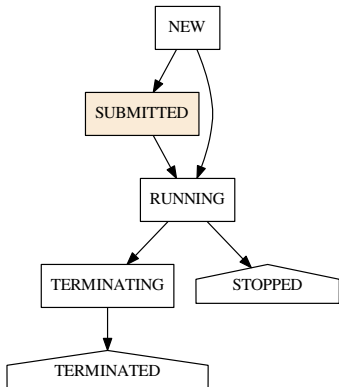

## Application lifecycle: state **NEW**

**NEW** is the state of “just created” Application objects.

The Application has not yet been sent off to a compute resource: it only exists locally.

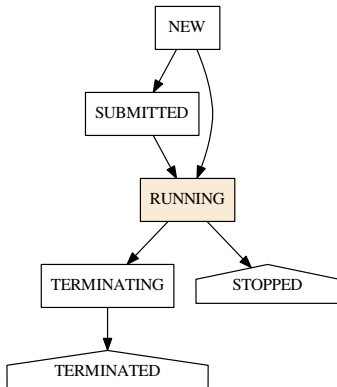

## Application lifecycle: state SUBMITTED

*SUBMITTED* applications have been successfully sent to a computational resource.

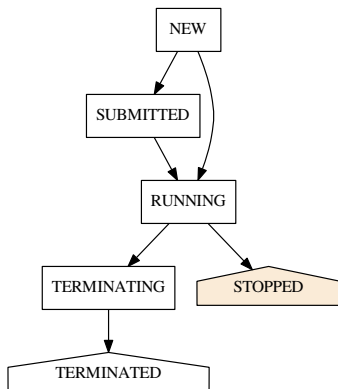

(The transition to *RUNNING* happens automatically, as we do not control the remote execution.)

## Application lifecycle: state **RUNNING**

*RUNNING* state happens when the computational job associated to an application starts executing on the computational resource.

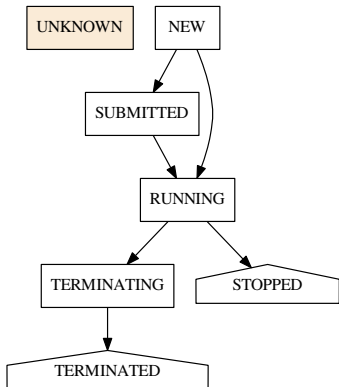

## Application lifecycle: state STOPPED

A task is in *STOPPED* state when its execution has been blocked at the remote site and GC3Pie cannot recover automatically.

User or sysadmin intervention is required for a task to get out of *STOPPED* state.

## Application lifecycle: state UNKNOWN

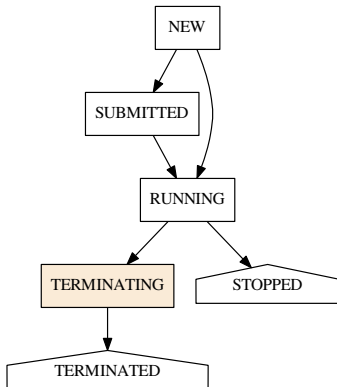

A task is in *UNKNOWN* state when GC3Pie can no longer monitor it at the remote site.

(As this might be due to network failures, jobs *can* get out of *UNKNOWN* automatically.)

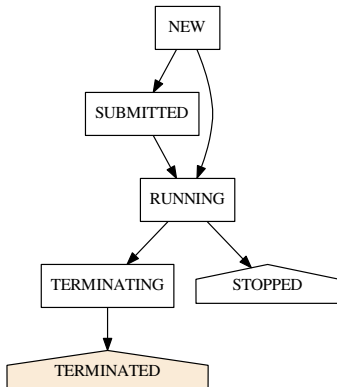

## Application lifecycle: state **TERMINATING**

*TERMINATING* state when a computational job has finished running, for whatever reason.

(Transition to *TERMINATED* only happens when `fetch_output` is called.)

## Application lifecycle: state **TERMINATED**

A job is *TERMINATED* when its final output has been retrieved and is available locally.

The exit code of *TERMINATED* jobs can be inspected to find out whether the termination was successful or unsuccessful, or if the program was forcibly ended.

## Post-processing

## Post-processing features, I

When the remote computation is done, the `terminated` method of the application instance is called.

The path to the output directory is available as `self.output_dir`; if `stdout` and `stderr` have been captured, the **relative** paths to the capture files are available as `self.stdout` and `self.stderr`.

## Post-processing features, II

For example, the following code logs a warning message if the standard error output is non-empty:

```
class MyApp(Application):  
    # ...  
    def terminated(self):  
        stderr_file = self.output_dir+"/"+self.stderr  
        stderr_size = os.stat(stderr_file).st_size  
        if stderr_size > 0:  
            gc3libs.log.warn(  
                "Application %s reported errors!", self)
```

### **Exercise 6.A:**

In the `gasset.py` script from Exercise 2.C, modify the `GassetApp` application to move the output picture file into directory `/home/ubuntu/pictures`. You might need to store the output file name to have it available when the application has terminated running.

(You might want to check out <http://stackoverflow.com/a/8858026/459543> if you're unsure how to move/rename a file with Python.)

## Termination status

## A successful run or not?

There's a *single TERMINATED state*, whatever the task outcome. You have to inspect the “return code” to determine the cause of “task death”.

Attribute ‘`.execution.returncode`’ provides a numeric termination status (with the same format and meaning as the POSIX termination status).

The termination status combines two fields: the “termination signal” and the “exit code”.

## Termination signal, I

The `.execution.signal` instance attribute is non-zero if the program was killed by a signal (e.g., memory error / segmentation fault).

The `.execution.signal` instance attribute is zero only if the program run until termination. (**Beware!** This does not mean that it run *correctly*: just that it halted by itself.)

## Termination signal, II

Read `man 7 signal` for a list of OS signals and their numeric values.

**Note that GC3Pie overloads some signal codes (unused by the OS) to represent its own specific errors.**

For instance, if program `app` was cancelled by the user, `.execution.signal` will take the value 121:

```
>>> print(app.execution.signal)
121
```

*Reference:* [https://github.com/uzh/gc3pie/blob/master/gc3libs/\\_\\_init\\_\\_.py#L1579](https://github.com/uzh/gc3pie/blob/master/gc3libs/__init__.py#L1579)

## Exit code

The `.execution.exitcode` instance attribute holds the numeric exitcode of the executed command, or `None` if the command has not finished running yet.

**Note that the `.execution.exitcode` is guaranteed to have a valid value only if the `.execution.signal` attribute has the value 0.**

The `.execution.exitcode` is the same exitcode that you would see when running a command directly in the terminal shell. (By convention, code 0 is successful termination, every other value indicates an error.)

## **Exercise 6.B:**

Modify the `gasset` script so that, when a `GassetApp` task has terminated execution, it prints:

- whether the program has been killed by a signal, and the signal number;
- whether the program has terminated by exiting, and the exit code.

## Application-specific configuration

Application classes may be tagged so that parts of the configuration file can be overridden just for them.

Suppose you tag the `GassetApp` class by giving it this name:

```
class GassetApp(Application):  
    application_name = 'gasset'  
    ...
```

then you can provide a specific VM image just for “gasset” applications:

```
# in the GC3Pie config file:  
[resource/sciencecloud]  
# [...]   
image_id=2b227d15-8f6a-42b0-b744-ed52ebe59f7  
gasset_image_id=0cca5346-ca12-4cb4-8007-8875c10cce02
```

Other configuration items that can be specialized are:

`instance_type`, `user_data` (cloud), and `prolog_file`, `epilog_file` (batch-systems).

## Global post-processing

Further options for customizing a session-based script:

`before_main_loop(self)` to execute some code *before* the submission of the jobs.

`after_main_loop(self)` to execute some code *after* the main loop. A list of all Application objects is available in the `self.session.tasks.values()` list.
